# 1 Data

Table 2 and 3 give an overview of the observations by data source type and age group. The detailed information on country-specific data series names and the assigned data source types for each age group are in the Supplementary Tables 22 (0–1), 23 (1–4), 24 (0–4), 25 (5–9), 26 (10–14), 27 (15–19), 28 (20–24). Data source types group data series with similar characteristics, such as data collection method, survey sampling design, and data reporting method.

We categorized all data sources into eight types for data under age five. For age groups under five. Specifically, the groupings of data series into different data source types are:

- Census Indirect: census based on summary birth histories;
- Demographic and Health Surveys (DHS) Direct: standard DHS with full birth histories;
- Multiple Indicator Cluster Surveys (MICS) Direct: MICS based on full birth histories;
- MICS Indirect: MICS based on summary birth histories;
- Other DHS Direct: Interim DHS, Special DHS, DHS AIDS Indicator Survey, DHS Malaria Indicators Survey, National DHS, World Fertility Survey, and surveys with similar sampling design and based on full birth histories;
- Others Direct: census direct, Reproductive Health Survey, Pan-Arab Programme on Family Health, National MICS, panel data, and national reports, based on full birth histories;
- Others Indirect: all types of DHS surveys, Reproductive Health Surveys, and national reports, based on summary birth histories

For data above age five, we classified all data sources into three types:

- Demographic and Health Surveys (DHS) Direct: including standard DHS;
- Others Direct: including Multiple Indicator Cluster Surveys (MICS), World Health Surveys (WHS), and Panel data;
- Vital Registration (VR) or Sample Registration System (SRS).

Data source	Age group		
	0–1	1–4	0–4
Census Indirect	5	0	5
DHS Direct	1479	1370	0

## 2 Data pre-processing

The database we use for model fitting (summarized in Section 1) is based on multiple data quality assessments and pre-processing steps.

Data source	Age group			
	5–9	10–14	15–19	20–24
DHS Direct	1,038	1,015	834	834
Others Direct	568	550	266	267
VR/SRS	3,702	3,647	3,745	3,723
<b>Total</b>	<b>5,308</b>	<b>5,212</b>	<b>4,845</b>	<b>4,824</b>
<b>Countries with data</b>	190	190	178	179
<b>Reference year range</b>	1954–2021	1954–2021	1958–2021	1958–2021

Table 3: **Distribution of observations by data source type and age group for children, adolescents, and youth aged 5–24.** Direct: data obtained from full sibling histories. Others Direct: data from recent household deaths reported in censuses and large-scale surveys.

## 2.1 Extraction by data source type

**Vital registration data** Nationally representative vital registration data were extracted from the WHO mortality database and the Human Mortality Database (1; 2). Completeness of death registration data for children below age five was estimated as the reported under-five mortality rate (U5MR) in vital registration data divided by the corresponding UN IGME estimate, which may rely on other data sources, such as surveys and census data. We estimated the completeness of death registration for the age groups 5–14 and 15–24 using death distribution methods, comparing the age distribution of deaths between two censuses with the age distribution of the population enumerated (3). The stochastic standard error of the observation was calculated using the Poisson approximation based on the number of births or the population turning 5 or 15 in a given year, estimated from the 2022 World Population Prospects (WPP) (4). We also included estimates from sample vital registration systems in India (5) and Bangladesh (6), the Chinese national mortality surveillance system (7), and the Rapid Mortality Surveillance in South Africa (8).

**Birth and sibling histories in surveys** Data from full birth histories collected in DHS, MICS, World Health Surveys, World Fertility Surveys, Reproductive Health Surveys, and selected surveys from the Pan-Arab Programme on Family Health were used to compute sex ratios for children and adolescents below age 15, for periods of varying lengths, optimised to capture shorter-term changes for country-years with sufficient information (9). Data from full sibling survival histories from DHS and MICS were used to estimate the sex ratio in youth aged 15–24. In all age groups, the sampling variance was calculated using the Jackknife estimation to account for the survey sample design. Indirect methods based on the number of children ever born and surviving, called summary birth histories, were used for children below age five.

**Censuses** Reports on recent household deaths were used to compute sex-specific estimates. The calculation of age-specific mortality rates was derived from standard life table methods. Data from the summary birth histories in censuses were also used for children under five.

## 2.2 Adjustments for the incompleteness of death registration

Vital registration data were extracted from the WHO mortality database<sup>1</sup>. When available, the latest estimates from the Human Mortality Database (HMD)<sup>2</sup> were also added. We assumed that death registration was complete in 38 countries included in the HMD. For the other countries, we evaluated the completeness based on “death distribution methods” (DDMs). The VR data were only adjusted for completeness of death reporting for mortality data above age 5. Loess regression (for smaller gaps in years) and linear interpolation (for gaps greater than five years) were applied to generate the time series using the available estimates of child completeness to impute completeness in years when vital registration data were unavailable. Table 11 presents the completeness estimates by country-year.

<sup>1</sup>[https://www.who.int/healthinfo/mortality\\_data/en/](https://www.who.int/healthinfo/mortality_data/en/)

<sup>2</sup><https://www.mortality.org/>

DDMs compare the age distribution of deaths in the VR with the age distribution of the population enumerated in censuses to estimate the fraction of deaths that are reported. Three methods are applicable when two censuses are available and deaths have been recorded in the intercensal period: the generalized growth balance method (GGB) (10; 11), the synthetic extinct generation method (SEG) (12), and a combination of the two, called the hybrid method (or GGB>SEG). All methods are well described in the book *Tools for Demographic Estimation* (13), with Excel spreadsheets to facilitate their use. We employed here the GGB>SEG approach, which has been shown to perform better than the GGB and SEG methods used separately (14). Completeness was estimated for each country for periods between pairs of recent censuses for which an age distribution of the population was available in the Demographic Yearbook. After the last census, it is impossible to estimate completeness with death distribution methods, so completeness levels were kept constant until 2021.

Using the DDM package in R (15), we separately estimated completeness for males and females. Vital statistics were excluded when the estimated completeness was less than 80% (for at least one sex), adjusted when completeness was between 80% and 95%, and included without adjustment when completeness was greater than or equal to 95%. The VR data were adjusted as follows:

$$\text{adjusted VR data} = \frac{\text{original VR data}}{\text{completeness}}$$

Completeness was assumed to be invariant by age in the age group 5-24. In a few countries, vital registration data were incorporated to estimate mortality above age 5, despite being deemed too incomplete to be used for under-five mortality. The completeness of death registration could be lower among children due to common under-reporting of neonatal deaths (16). In some countries (e.g. Brazil, Republic of Korea, Syria, Turkey, Singapore, Bahrain, and Sri Lanka), we have preferred not to adjust upwards the deaths reported to vital statistics, either because of large migrations flows that could invalidate the method, or because published studies had investigated the completeness of death registration (see (17) for further details).

Uncertainty was added in countries with adjusted VR data to account for the uncertainty associated with the completeness estimate. Murray et al. (2010) demonstrate that uncertainty intervals around completeness estimates from DDM are large, roughly about 25% (18). This is partly because death distribution methods are based on assumptions often poorly respected in practice (e.g. constant under-registration by age). We proceeded as follows:

1. The sex-specific completeness was simulated with a uniform distribution: Uniform(completeness - 25%, completeness + 25%).
2. The number of deaths with additional uncertainty was simulated by:  $\text{Poisson}\left(\frac{\text{reported deaths}}{\text{simulated completeness}}\right)$
3. The sex-specific mortality rates with additional uncertainty were simulated using a standard life table approach with the simulated number of deaths from the previous step.

## 2.3 Exclusion criteria

Before fitting the observations to the Bayesian model, we excluded data points based on the following rules:

- Exclude observations with sex ratio outside [0.1, 10] for ages under five, and outside [0.1, 10] for ages above five (refer to Table 4 for the number of observations that fall outside the intervals by age group).
- Exclude observations during national crisis periods.
- Exclude observations from surveys or censuses with strong evidence of poor data quality.

Table 4 summarizes the excluded data points by each exclusion criterion.

Data series were excluded from the sex-specific analysis when the review conducted to develop estimates for both sexes had concluded that there was substantial evidence of recall errors. The procedures to identify recall errors in surveys and censuses are discussed in (19) for the age group 0-4, (20) for the age group 5-14 and (17) for the age group 15-24. We have not used a grading method to assess the quality of survey or census data, but a series of tests are put in place to identify sources of erroneous data. For example, in censuses, we assess parity ratios from one survey to the next to detect omissions of children in summary birth histories (21). In full birth histories from surveys, we use

Exclusion criteria	Age group						
	0–1	1–4	0–4	5–9	10–14	15–19	20–24
Sex ratio outside [0.2, 5]	530	2,033	562	–	–	–	–
Sex ratio outside [0.1, 10]	–	–	–	14	105	36	66
During national crisis	237	235	240	57	57	46	46
<b>Total</b>	<b>767</b>	<b>2,263</b>	<b>801</b>	<b>71</b>	<b>162</b>	<b>82</b>	<b>111</b>
<b>Percentage of total</b>	<b>0.9%</b>	<b>2.3%</b>	<b>1.0%</b>	<b>1.1%</b>	<b>2.4%</b>	<b>1.4%</b>	<b>1.8%</b>

Table 4: **Excluded observation distribution by data exclusion criteria and age group.** The total number of excluded observations may not be the sum of the excluded number of data under each criterion because some excluded data satisfy more than one criterion.

consistency checks such as the ratio between neonatal and post-neonatal mortality and the distribution of deaths by day (22). In sibling survival histories, we examine the plausibility of the relationship between the probabilities  $_{10}q_{15}$  and  $_{5}q_0$  against high-quality life tables from Health and Demographic Surveillance Systems (HDSS) and the Human Mortality Database (17).

### 3 Methods for sex ratio for five-year age groups 5–24

We provide a full model specification in this web appendix. The statistical model for estimating the sex ratio of mortality for 0–1, 1–4, and 0–4 are detailed in (23).

In the following Section 3.1 and Section 3.2, we summarize the model to estimate the sex ratio of male mortality to female mortality for the age group for age groups 5–9, 10–14, 15–19, and 20–24. Since the same model is applied to each age group, we omit the index for age group, and all the notations in Section 3.1 and Section 3.2 are age specific.

The outcome of interest is  $\exp\{\Psi_{c,t}\}$ , the sex ratio of mortality rate in the country  $c$  in year  $t$ , where  $\Psi_{c,t}$  is the log of the sex ratio. For the country and year indexes,  $c \in \{1, \dots, k\}$  with  $k = 200$  referring to the total number of countries, and  $t \in \{1, \dots, j\}$  with  $j = 72$  indicating the individual years from 1950 ( $t = 1$ ) to the year 2021 ( $t = j$ ). Throughout the report,  $\mathcal{N}(\mu, \sigma^2)$  refers to a normal distribution with mean  $\mu$  and variance  $\sigma^2$  and  $\mathcal{U}(a, b)$  refers to a continuous uniform distribution with lower and upper bounds at  $a$  and  $b$  respectively.

The complete data process and model overview are in the flow chart Figure 1. The detailed explanations of the model and the posterior distribution are in the rest of this section.

#### 3.1 Data model

Let  $z_i$  to be the  $i$ th observed sex ratio and  $y_i = \log(z_i)$ . We have the model:

$$y_i = \Psi_{c[i],t[i]} + \varepsilon_i, \text{ for } i \in \{1, \dots, n\}, \quad (1)$$

$$\varepsilon_i | \omega_{s[i]} \sim \mathcal{N}(0, u_i^2 + \omega_{s[i]}^2), \quad (2)$$

$$\omega_s = 0, \text{ for } s = m, \quad (3)$$

$$\tau_{\omega,s} = \omega_s^{-2} \sim \mathcal{PC}(z, 0.01), \text{ for } s \in \{1, \dots, m-1\}. \quad (4)$$

For a certain age group, the observations of the sex ratio are indexed by  $i \in \{1, \dots, n\}$ .  $y_i$  denotes the  $i$ th log of observed sex ratio of mortality rate in country  $c[i]$  in year  $t[i]$  and is modeled on the log-scale.  $\exp\{\Psi_{c,t}\}$  is the outcome of interest, the true sex ratio of mortality rate, in country  $c$  in year  $t$ .  $\varepsilon_i$  is the error term for  $y_i$ .

The error term  $\varepsilon_i$  follows a normal distribution as shown in Equation 2. The variance is the sum of two parts: (i) known stochastic/sampling error variance  $u_i^2$ , (ii) unknown non-sampling error variance  $\omega_{s[i]}^2$  that differs by data source type  $s$ . The sampling variance is pre-calculated using the Jackknife resampling method by the R-package **demogurv**<sup>3</sup> to account for the uncertainty due to the sample design of the surveys. We assume the non-sampling error for VR/SRS

<sup>3</sup>Available at: <https://github.com/mrc-ide/demogurv>. Accessed on July 27th, 2020.

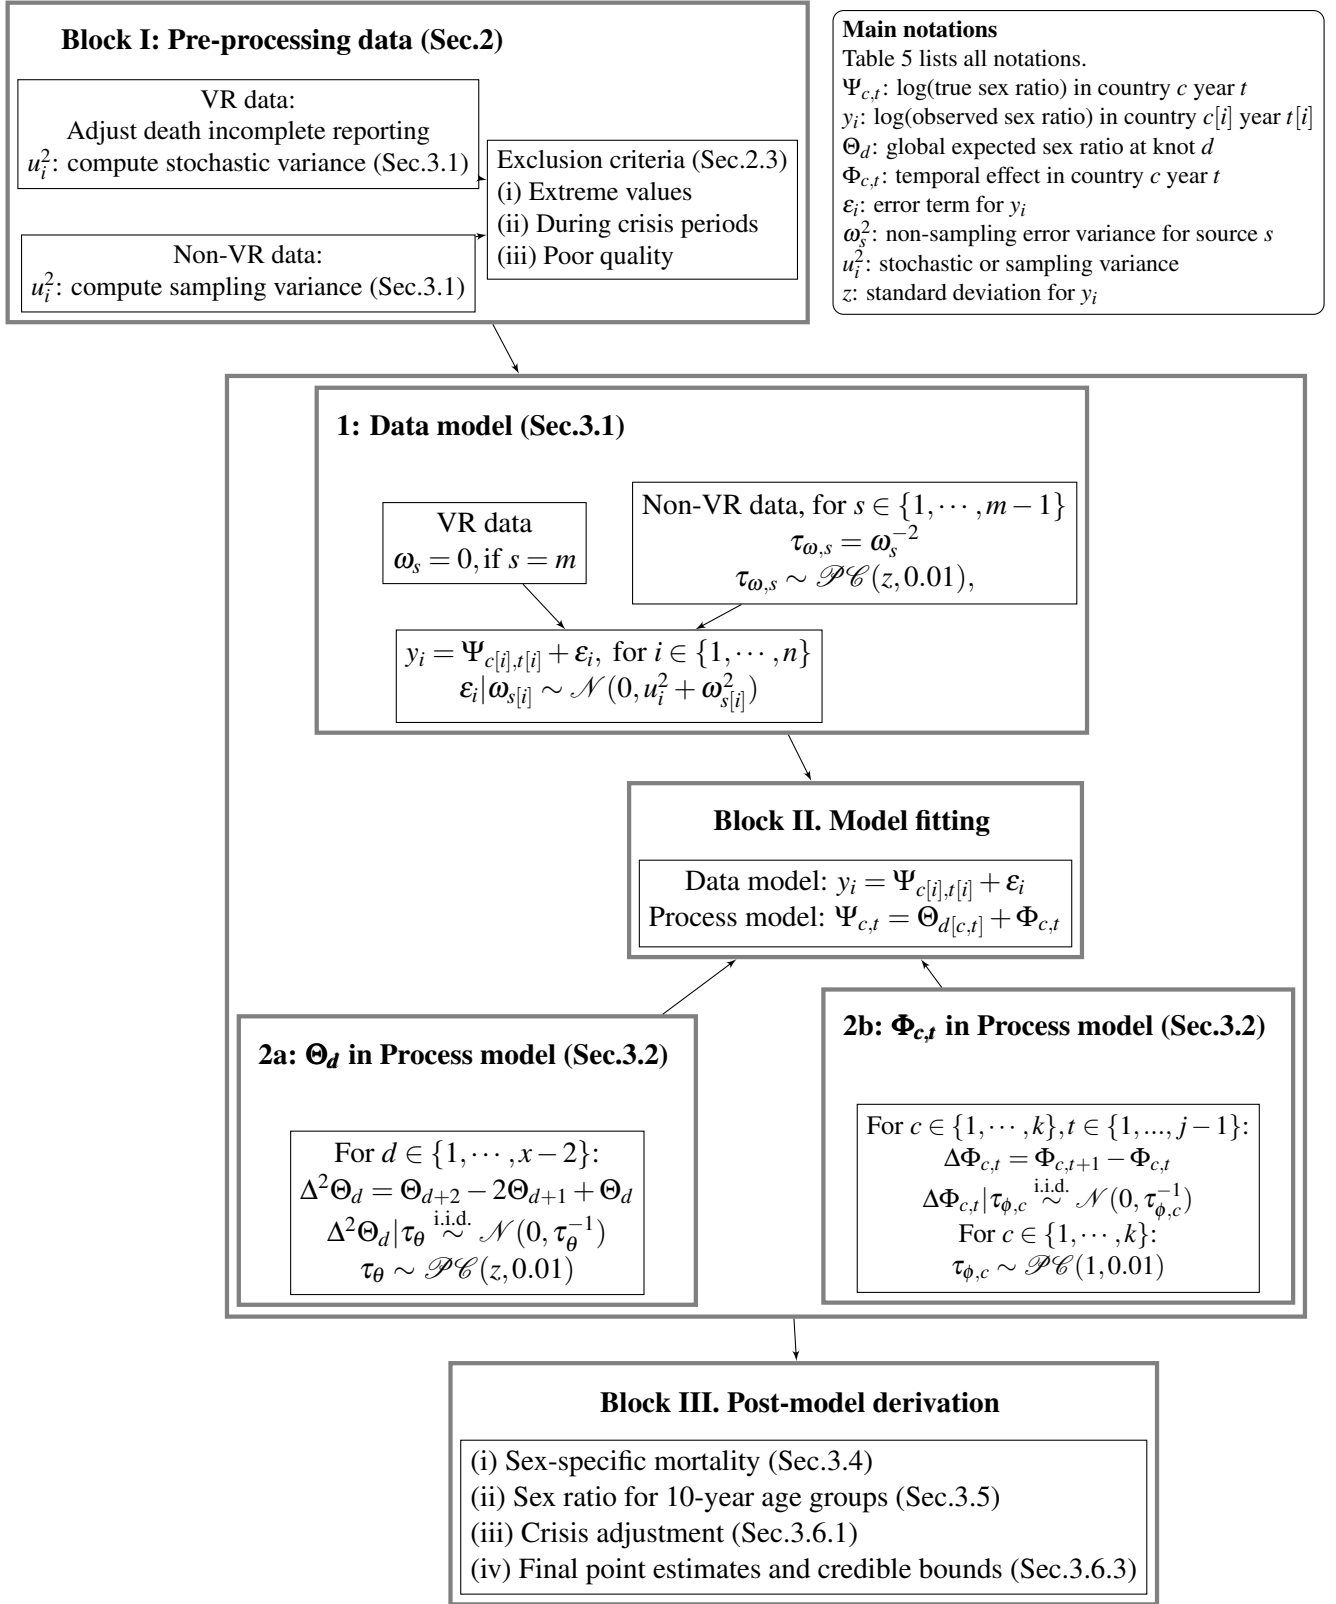

Figure 1: **Data and model process overview.** This flow chart summarizes the major steps of pre-processing data (Block I), the Bayesian modelling steps (Block II), where  $\Psi_{c,t}$  refers to the true sex ratio of mortality on the log-scale, and the post-model derivation (Block III).

data is zero (i.e.  $s = m$  refers to data source type VR/SRS). For data from non-VR/SRS source types, we estimate non-sampling error variances that vary across data source types ( $s \in \{1, \dots, m-1\}$  refer to the set of non-VR/SRS data source types).  $z$  is the standard deviation of  $y_i$ . We assign Penalized Complexity (PC) priors for the precision parameter  $\tau_{\omega,s}$  (24).

The Bayesian estimates are pooled towards informative observations and are less influenced by weakly informative observations. Retrospective estimates based on surveys and recent household deaths could be affected by differential underreporting of deaths in boys or girls. However, comparisons of birth histories in surveys with prospective demographic surveillance did not find that data quality markers were associated with the sex of the child (25). In sibling survival histories, there is evidence that underreporting of deaths is more frequent for brothers than sisters (26), so our estimates of the sex ratio in the age group 15–24 could be biased slightly downwards in countries where sibling data are our primary data source.

PC priors are default priors assigned to precision parameters used in the R-package R-INLA, which we used for Bayesian inference (refer to Section 3.3, paragraph Statistical computation). The main advantages of PC priors are that they are invariant to reparameterizations and have excellent robustness properties according to (24).

### 3.2 Process model

The process model for  $\Psi_{c,t}$  is defined as:

$$\Psi_{c,t} = \Theta_{d[c,t]} + \Phi_{c,t}, \quad (5)$$

where  $\Theta_{d[c,t]}$  is the global expected sex ratio evaluated at the total mortality rate (female and male combined) for country  $c$  in year  $t$  (more explanations in the next paragraph).  $\Phi_{c,t}$  is the year-by-year fluctuation around the global relation, capturing the intra-country temporal correlation between country-specific observations.

$\Theta_{d[c,t]}$  models the global non-linear relation between  $\Psi_{c,t}$  and the total mortality rate in country  $c$ , year  $t$ . Specifically, let  $V_{c,t}$  denote the log of total (male and female combined) mortality rate for country  $c$  year  $t$ , taken from the UN Inter-agency Group for Child Mortality Estimation (UN IGME) 2022 estimates (27). We define a grid of values  $\kappa_d$  for  $d \in \{1, \dots, x\}$ .  $x$  is the number of grid points where  $\Theta_d$  is evaluated.  $x = 310$  for age group 5–9,  $x = 230$  for age group 10–14,  $x = 260$  for age group 15–19,  $x = 275$  for age group 20–24.  $x$  differs across age groups because the range of total mortality and country-years with data in different age groups varies. For all the five-year age groups from 5 to 24, we set  $\kappa_1 = \log(1/1000)$ , corresponding to 1 death per 1000 population on the log scale. We set  $\kappa_x$  as the 99th percentile of  $V_{c,t}$  across all country-years with data in each age group. We match each  $V_{c,t}$  to the  $\kappa_d$  with the smallest absolute difference from  $V_{c,t}$ , denoting the  $d$ th index for country-year  $c, t$  as  $d[c, t]$ . To model the relation between  $\Theta_d$  and  $\kappa_d$ , we use a second-order random walk (RW2) process. We assume  $\Theta_d$  is constant outside the range of  $\kappa_1$  and  $\kappa_x$  across all  $c$  and  $t$ . In particular,

$$\Delta^2 \Theta_d = \Theta_{d+2} - 2\Theta_{d+1} + \Theta_d, \text{ for } d \in \{1, \dots, x-2\} \quad (6)$$

$$\Delta^2 \Theta_d | \tau_\theta \stackrel{\text{i.i.d.}}{\sim} \mathcal{N}(0, \tau_\theta^{-1}), \text{ for } d \in \{1, \dots, x-2\}, \quad (7)$$

$$\tau_\theta \sim \mathcal{PC}(z, 0.01). \quad (8)$$

We assign a Penalized Complex (PC) prior to the global precision parameter  $\tau_\theta$ :

$$\tau_\theta \sim \mathcal{PC}(z, 0.01). \quad (9)$$

where  $z$  is the standard deviation of  $y_i$ . The PC prior is a vague prior. (24) documented the PC prior specification in detail.

Figure 2 illustrates the RW2 model results for  $\Theta_d$  for age groups 5–9, 10–14, 15–19 and 20–24. The estimated model results (in purple) align with the empirical relationships demonstrated in loess curves. When developing our estimates, we explored modelling  $\Theta_d$  on a regional level instead of on a global level. We decided against the use of a regional model for three reasons. First, some outlying countries with specific discrimination practices or distinct cause-specific mortality patterns would no longer be apparent, as we would lose the comparison with other countries in other regions with the same mortality level. Second, it was not easy to interpret the regional trends, and we could no

longer examine national deviations in the same consistent framework between birth and 25th birthday since the model for U5MR uses a global reference. Third, the uncertainty around estimates was slightly increased with a regional model.

$\Phi_{c,t}$  models the discrepancy between  $\Psi_{c,t}$  and global trend  $\Theta_d$ . We use a first-order random walk (RW1) model for  $\Phi_{c,t}$  and assign a PC prior to country-specific precision parameter  $\tau_{\phi,c}$ :

$$\Delta\Phi_{c,t} = \Phi_{c,t+1} - \Phi_{c,t}, \text{ for } c \in \{1, \dots, k\}, t \in \{1, \dots, j-1\} \quad (10)$$

$$\Delta\Phi_{c,t} | \tau_{\phi,c} \stackrel{\text{i.i.d.}}{\sim} \mathcal{N}(0, \tau_{\phi,c}^{-1}), \text{ for } c \in \{1, \dots, k\}, t \in \{1, \dots, j-1\}, \quad (11)$$

$$\tau_{\phi,c} \sim \mathcal{PC}(1, 0.01), \text{ for } c \in \{1, \dots, k\}. \quad (12)$$

The sum-to-zero constraint is imposed on  $\Phi_{c,t}$  so that the precision matrix is full-rank:

$$\sum_{t=1}^j \Phi_{c,t} = 0, \text{ for } c \in \{1, \dots, k\}. \quad (13)$$

### 3.3 Model summary

**Notations** Table 5 summarizes the notation and indexes used in Section 3.1 and Section 3.2.

#### Data model

$$\begin{aligned} y_i &= \Psi_{c[i],t[i]} + \varepsilon_i, \text{ for } i \in \{1, \dots, n\}, \\ \varepsilon_i | \omega_{s[i]} &\sim \mathcal{N}(0, u_i^2 + \omega_{s[i]}^2), \\ \omega_s &= 0, \text{ for } s = m. \end{aligned}$$

#### Process model

$$\begin{aligned} \Psi_{c,t} &= \Theta_{d[c,t]} + \Phi_{c,t}, \\ \Delta^2\Theta_d &= \Theta_{d+2} - 2\Theta_{d+1} + \Theta_d, \text{ for } d \in \{1, \dots, x-2\} \\ \Delta^2\Theta_d | \tau_\theta &\stackrel{\text{i.i.d.}}{\sim} \mathcal{N}(0, \tau_\theta^{-1}), \text{ for } d \in \{1, \dots, x-2\}, \\ \Delta\Phi_{c,t} &= \Phi_{c,t+1} - \Phi_{c,t}, \text{ for } c \in \{1, \dots, k\}, t \in \{1, \dots, j-1\} \\ \Delta\Phi_{c,t} | \tau_{\phi,c} &\stackrel{\text{i.i.d.}}{\sim} \mathcal{N}(0, \tau_{\phi,c}^{-1}), \text{ for } c \in \{1, \dots, k\}, t \in \{1, \dots, j-1\}. \end{aligned}$$

**Prior distributions** Non-informative priors are assigned to hyper-parameters:

$$\begin{aligned} \tau_{\omega,s} = \omega_s^{-2} &\sim \mathcal{PC}(z, 0.01), \text{ for } s \in \{1, \dots, m-1\}, \\ \tau_\theta &\sim \mathcal{PC}(z, 0.01), \\ \tau_{\phi,c} &\sim \mathcal{PC}(1, 0.01), \text{ for } c \in \{1, \dots, k\}. \end{aligned}$$

**Statistical computation** We use the Integrated Nested Laplace Approximation (INLA) for Bayesian inference (28). We use the R-package R-INLA (29) to implement the INLA estimation procedure. The statistical source code is available upon request.

### 3.4 Derivation of sex-specific mortality

For each country-year, we calculated the sex-specific mortality by fulfilling (i) the number of female and male deaths sum up to the total number of deaths based on the life-table method; and (ii) the ratio of male to female mortality equals the sex ratio estimates from the Bayesian model. Given the total mortality rates  $Q_{c,t}$  and the estimated sex ratio

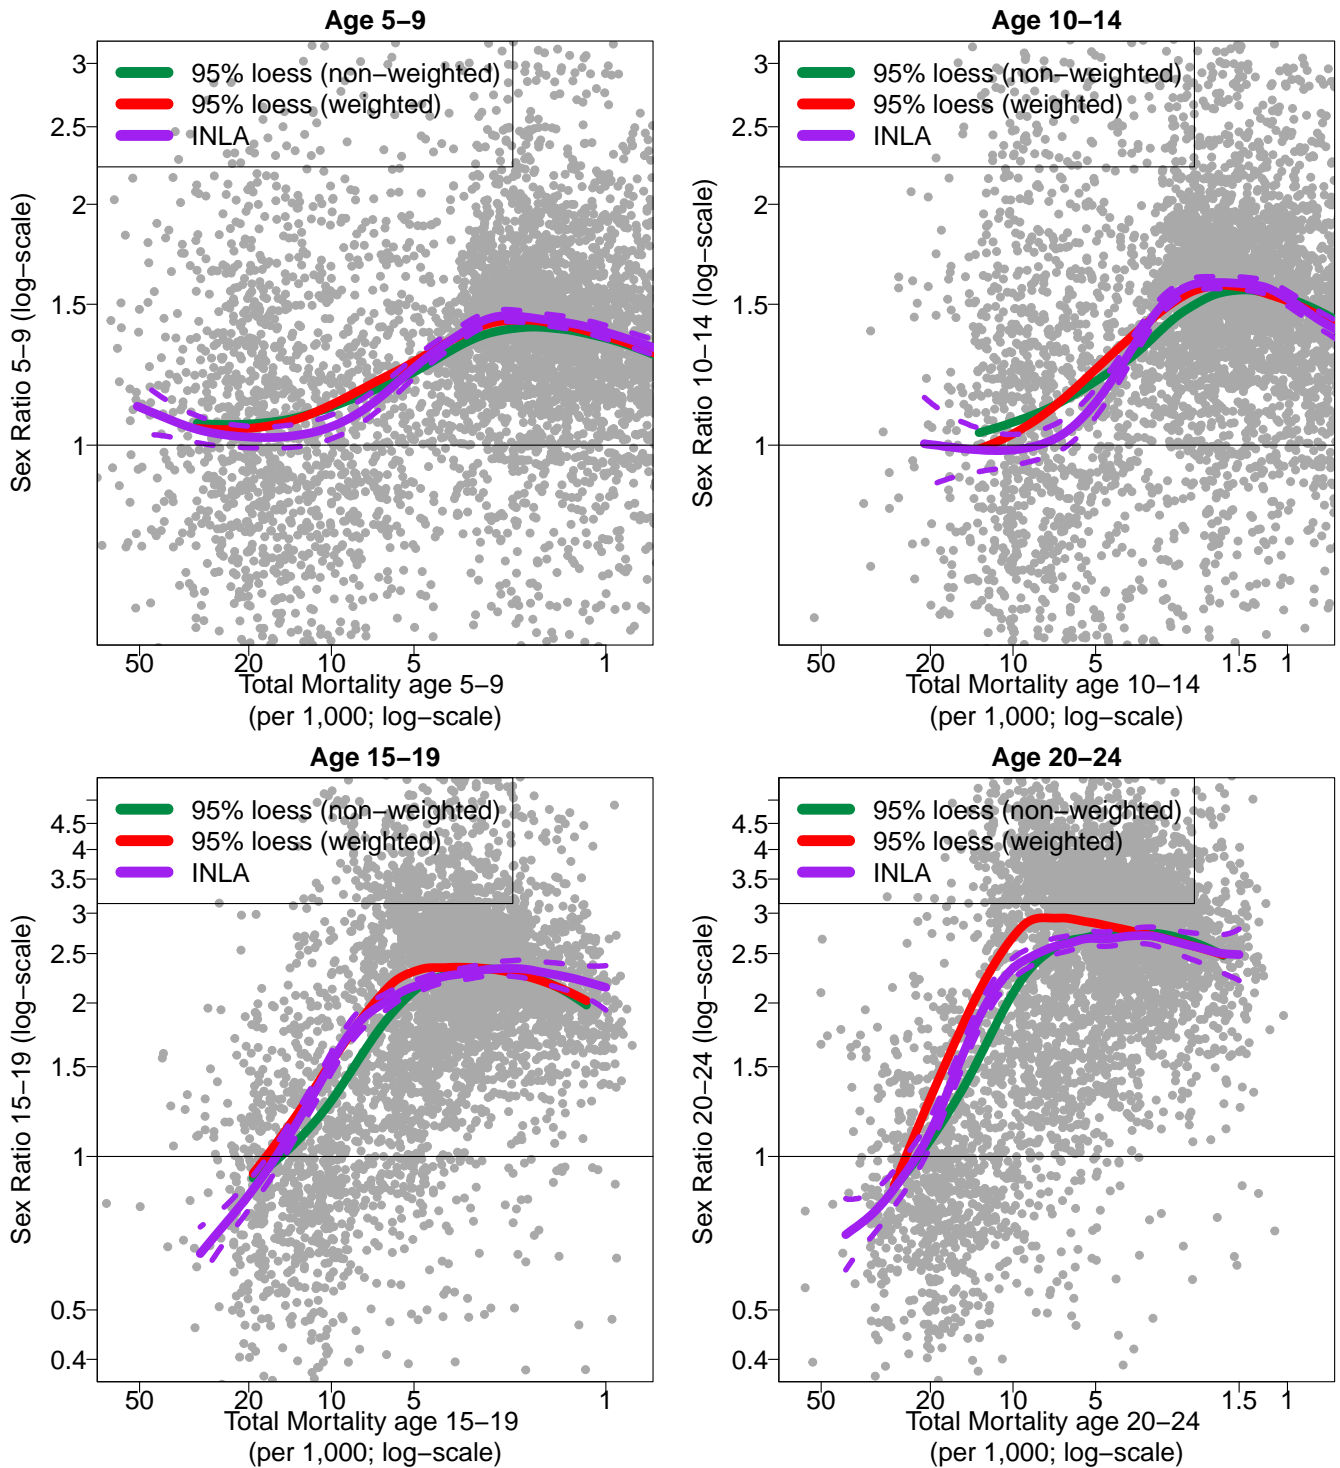

Figure 2: **Global relation between total mortality and sex ratio.** Green curves are loess fittings (using a re-descending M estimator with Tukey’s biweight function). Red curves are symmetric loess by weighting data points by the reverse of their sampling error variances. Purple solid curves are the mean of the model fittings using the RW2 model, and dashed curves are 90% uncertainty intervals.

Symbol	Description
<i>Indexes</i>	
$i$	Indicator for observations across all country-years, $i \in \{1, \dots, n\}$ .
$c$	Indicator for country, $c \in \{1, \dots, k\}$ , where $k = 200$ . $c[i]$ refers to the country index of observation $i$ .
$t$	Indicator for year, $t \in \{1, \dots, j\}$ , where $j = 72$ . $t = 1$ corresponds to the year 1950 and $t = j$ to the year 2021. $t[i]$ refers to the year index of observation $i$ .
$s$	Indicator for data source type, $s \in \{1, \dots, m\}$ , where $m = 3$ . $s = 1$ corresponds to data source type DHS, $s = 2$ to others, and $s = 3$ to VR/SRS.
$d$	Indicator for the $d$ th unique value of the total mortality rate $\kappa_d$ and corresponding global expected sex ratio $\Theta_d$ . $d[c, t]$ refers to the index based on total mortality in country-year $c, t$ . More explanations are in the row of $\kappa_d$ .
<i>Known quantities</i>	
$z_i$	$i$ th observed sex ratio of mortality rate for country $c[i]$ in year $t[i]$ with data source type $s[i]$ .
$y_i$	$y_i = \log(z_i)$ .
$u_i^2$	The $i$ th sampling error variance for $y_i$ .
$z$	The standard deviation of $y_i$ .
$Q_{c,t}$	The total mortality rate for country $c$ in year $t$ (20).
$V_{c,t}$	$V_{c,t} = \log(Q_{c,t})$
$\kappa_d$	Grid of $V_{c,t}$ where $\Theta_d$ is evaluated for $d \in \{1, \dots, x\}$ , and $x = 260$ . $\kappa_1 = \log(1/1000)$ , i.e. log of 1 death per 1000 population (same $\kappa_1$ value for all age groups). $\kappa_x$ is the 99th percentile of $V_{c,t}$ across all country-years with data (different $\kappa_x$ values across age groups).
<i>Unknown parameters</i>	
$\Psi_{c,t}$	The true log of sex ratio of mortality rate for country $c$ , year $t$ .
$\Theta_{d[c,t]}$	The global expected sex ratio evaluated at $\kappa_d$ .
$\Phi_{c,t}$	The year-by-year within country discrepancy between $\Psi_{c,t}$ and $\Theta_d$ .
$\tau_{\omega,s}$	The precision parameter for non-sampling error variance with data source type $s$ .
$\tau_{\theta}$	The precision parameter for the second-order increment $\Delta^2 \Theta_d$ .
$\tau_{\phi,c}$	The country-specific precision parameter for the first-order increment $\Delta \Phi_{c,t}$ for country $c$ .

Table 5: **Notation summary.**

of the mortality rates  $\Psi_{c,t}$ , we derive the sex-specific mortality rates as shown in Table 6. In this subsection, we omit the indexes for country  $c$  and year  $t$  and use superscripts  $[F]$  and  $[M]$  for male- and female-specific indicators.

To incorporate the uncertainties in the sex ratio of mortality, total mortality, and population sizes, the calculation steps in Table 6 are applied to each posterior sample of:

- Each posterior sample of the log of sex ratio  $\Psi$ : from the Bayesian model.
- Each trajectory of the total mortality  $Q$ : from (27) (not part of this modelling process).
- Each trajectory of the numbers of the total and male population ( $N$  and  $N^{[M]}$ ) at the beginning of a 5-year age group: from the UN WPP (4) (not part of this modelling process).

Table 6: **Derivation of sex-specific mortality rate for a 5-year age group.**

Step #	Description
1:	Initialize female and male mortality rates ${}^{(0)}Q^{[F]}$ and ${}^{(0)}Q^{[M]}$ with based on total mortality $Q$ and log of sex ratio $\Psi$ , and the proportion of males $N^{[M]}$ in the whole population $N$ at the beginning of a certain age group (e.g. for age group 15–19, the beginning of the age group is age 15): $w = N^{[M]}/N$ ; ${}^{(0)}Q^{[M]} = Q/(w + (1 - w)/\exp\{\Psi\})$ , ${}^{(0)}Q^{[F]} = {}^{(0)}Q^{[M]}/\exp\{\Psi\}$ ,
2:	Following the life table calculation, we compute the central rate of mortality <sup>4</sup> for the female, male, and total population (denoted as $m^{[F]}$ , $m^{[M]}$ , and $m$ respectively): ${}^{(0)}m^{[F]} = {}^{(0)}Q^{[F]}/(5(1 - {}^{(0)}Q^{[F]}/2))$ ${}^{(0)}m^{[M]} = {}^{(0)}Q^{[M]}/(5(1 - {}^{(0)}Q^{[M]}/2))$ ${}^{(0)}m = ({}^{(0)}m^{[F]}N^{[F]} + {}^{(0)}m^{[M]}N^{[M]})/N$ We use the usual approximation to compute $m$ values by assuming the average population size in each age group within one year is $N(1 - Q^*)$ , where $Q^*$ is $Q^{[F]}$ or $Q^{[M]}$ . The average population size for a 5-year age group within one year is approximated by $5N(1 - Q^*)$ .
3:	Compute the total mortality rate based on initial values: ${}^{(0)}Q = 5{}^{(0)}m/(1 + (5 - 5/2){}^{(0)}m)$
4:	Compute the relative difference between the given total mortality $Q$ with the calculated total mortality ${}^{(0)}Q$ : ${}^{(0)}re =  {}^{(0)}Q - Q /Q$
5:	<b>if</b> ${}^{(0)}re < 10^{-8}$ <b>then</b>
6:	<b>stop</b> Set ${}^{(0)}Q^{[F]}$ and ${}^{(0)}Q^{[M]}$ as the final sex-specific mortality rates. <b>else</b>
7:	<b>for</b> $g \in \{1, \dots, G\}$ <b>do</b>
8:	Simulate $10^5$ equally distributed male mortality rate within the interval $[{}^{(g-1)}Q^{[M]} - {}^{(g-1)}Q^{[M]}/10^{-3}, {}^{(g-1)}Q^{[M]} + {}^{(g-1)}Q^{[M]}/10^{-3}]$ . Denote each simulation as ${}^{(g)}Q_s^{[M]}$ for $s \in \{1, \dots, 10^5\}$ .
9:	Simulations for female mortality rates are: ${}^{(g)}Q_s^{[F]} = {}^{(g)}Q_s^{[M]}/\Psi$ for $s \in \{1, \dots, 10^5\}$ .
10:	Repeat steps 2–6 until ${}^{(g)}re < 10^{-8}$ .

### 3.5 Derivation of sex ratio for 10-year age groups

This subsection explains how we derived the sex ratio for 15–24 based on sex ratios 15–19 and 20–24. The same procedures apply to deriving the sex ratio for 5–14 based on sex ratios for 5–9 and 10–14.

The sex ratio for mortality rate from age group 15–24 is calculated from  $S_{1,c,t}$  and  $S_{2,c,t}$  through standard cohort equations. Sex-specific mortality rates for age groups 15–19 ( $a = 1$ ) and 20–24 ( $a = 2$ ) are derived as follows (omitting

<sup>4</sup>It is approximately equal to the average number of deaths each year at age  $x$  last birthday, divided by the average population at that age in the same year.

country  $c$  and year  $t$  subscripts, and using superscripts  $[F]$  and  $[M]$  for male- and female-specific indicators):

$$Q_a^{[M]} = \frac{Q_a}{w_a + \frac{1-w_a}{S_a}}, \text{ for } a \in \{1, 2\},$$

$$Q_a^{[F]} = \frac{Q_a^{[M]}}{S_a}, \text{ for } a \in \{1, 2\}.$$

$w_1$  refers to the proportion of males at the age of 15.  $w_2$  indicates the ratio of male survivors to age 19 over the total number of survivors up to age 19:

$$w_1 = \frac{N_1^{[M]}}{N_1},$$

$$w_2 = \frac{N_2^{[M]}}{N_2} = \frac{w_1(1 - Q_1^{[M]})}{1 - Q_1},$$

where  $N_1$  refers to the total population at age 15, and  $N_2$  is the number of survivors to age 19 (approximated by the population at age 15 times the mortality rate for age group 15–19).

Given the mortality rates for age groups 15–19 and 20–24 by sex, the sex-specific mortality rates for age group 15–24 are calculated as follows:

$$Q_3 = 1 - (1 - Q_1)(1 - Q_2),$$

for males and females, which are then used to produce sex ratios of mortality rate for the age group 15–24:

$$S_{3,c,t} = \frac{Q_{3,c,t}^{[M]}}{Q_{3,c,t}^{[F]}}.$$

### 3.6 Computation of final results

Throughout the project, we presented our results in the format of “point estimate [lower bound; upper bound]”. E.g. the age-sex-specific mortality rate and deaths are presented as  $Q_{a,c,t}^{P.E.}[Q_{a,c,t}^L; Q_{a,c,t}^U]$  and  $D_{a,c,t}^{P.E.}[D_{a,c,t}^L; D_{a,c,t}^U]$  respectively. We use superscripts  $[F]$  and  $[M]$  for male- and female-specific indicators. This section will explain how we derived each component in the result.

#### 3.6.1 Constructing posterior samples of outcomes that include crisis-related deaths and uncertainty in national-level mortality rate

All the indicators in this section are country-year-specific. Hence, we omit the indexes  $c$  and  $t$  for country and year for simplicity.

The sex-specific mortality rates and related deaths were adjusted in country-years to account for abrupt increases in mortality due to conflicts and disasters, which would otherwise not be present in the smoothed mortality curves obtained from the statistical model. No specific adjustment was made for the coronavirus disease 2019 (COVID-19) pandemic because the UN IGME did not find sufficient evidence to warrant a systematic adjustment for national both-sex estimates based on available data from over 110 countries in 2020 and over 80 countries in 2021 (27). Moreover, estimates from vital statistics data already reflected the potential disruptions introduced by the pandemic. Data were lacking in other countries without vital statistics to conclude on effects of the pandemic on sex differences in mortality below the age of 25.

Table 12 lists all the country-years with crisis adjustments by age groups. Crisis adjustments were made during the identified crisis periods in 36 countries for ages 0–4, 53 countries for ages 5–14, and 48 countries for ages 15–24 to account for crisis-related deaths.

The following criteria were used to identify crises:

1. The crisis was isolated to a few years,
2. Crisis deaths in each age group were  $>10\%$  of non-crisis deaths in this age group,

3. The crisis-specific risk of dying was greater than 0.2 per 1,000,
4. The number of crisis deaths in each age group was greater than 10.

To include crisis-related deaths in the crisis-free sex-specific estimates obtained from the model, we followed the procedures used by the UN IGME for adjusting national-level mortality rates (30; 27). The  $g$ -th posterior sample for sex-specific mortality rate including crisis-related deaths, denoted as  $^{(g)}Q(\text{full})_a^{[\text{sex}]}$ , is defined as follows for  $\text{sex} \in \{F, M\}$ :

$$^{(g)}Q(\text{full})_a^{[\text{sex}]} = \begin{cases} ^{(g)}Q(\text{crisis-free})_a^{[\text{sex}]} + Q(\text{crisis})_a^{[\text{sex}]}, & \text{if affected by crisis} \\ ^{(g)}Q(\text{crisis-free})_a^{[\text{sex}]} & \text{o.w.} \end{cases}$$

$Q(\text{crisis-free})_a^{(g)}$  is the  $g$ -th posterior sample of crisis-free country-year-age-sex-specific mortality rate that includes uncertainty in national-level mortality (Section 3.4).

$Q(\text{crisis})_a^{[\text{sex}]}$  is the country-year-age-sex-specific mortality rate due to crisis. No uncertainty of crisis-related mortality rate has been included in the final adjusted sex-specific mortality rate results. Age-sex distributions for conflict deaths were applied to estimates of total conflict deaths by country-year based on available distributions of conflict deaths by age and sex for specific conflicts (31). Estimated deaths for major natural disasters up to and including 2021 were obtained from the Emergency Events Database (EM-DAT), the International Disaster Database, which is maintained by the Centre for Research on the Epidemiology of Disasters (CRED)(32). Global Health Estimates (GHE) age-sex distributions were used. These are based on several studies of earthquake and tsunami deaths (31). Deaths due to armed conflict and violence are from the Armed Conflict Location and Event Data Project (ACLED) (33), the Uppsala Conflict Data Program (UCDP) for Battle-Related Deaths, Non-State Conflict Dataset (34), and One-sided Violence Dataset (34).

Posterior samples for the sex ratio of mortality rates (with crisis-related deaths), inclusive of uncertainty in the national-level death (including crisis-related deaths), were given by:

$$^{(g)}\exp\{\Psi(\text{full})\}_a = \frac{^{(g)}Q(\text{full})_a^{[M]}}{^{(g)}Q(\text{full})_a^{[F]}}.$$

### 3.6.2 Rounding

We kept three significant figures for all reported estimates and uncertainty intervals. We round the number of sex-specific deaths for each country-year to its nearest integer.

### 3.6.3 Constructing uncertainty intervals and point estimates

All the indicators in this section are country-year-specific. Hence, we omit the indexes  $c$  and  $t$  for country and year for simplicity. The 90% uncertainty intervals for  $\Psi(\text{full})_a$ ,  $Q(\text{full})_a$ , and  $D(\text{full})_a$ , denoted as  $[*^L; *^U]$ , are the 5th and 95th percentiles of the corresponding posterior samples:

$$\begin{aligned} *^L &= \text{percentile}_{5\%} \left\{ {}^{(1)}*, \dots, {}^{(G)}* \right\}, \\ *^U &= \text{percentile}_{95\%} \left\{ {}^{(1)}*, \dots, {}^{(G)}* \right\}. \end{aligned}$$

where  $*$  can be substituted with  $\Psi(\text{full})_a$ ,  $Q(\text{full})_a$ , and  $D(\text{full})_a$ .

The point estimates  $\exp\{\Psi(\text{full})\}_a^{\text{P.E.}}$  are combined with the point estimates of total mortality rate  $Q(\text{full})_a^{\text{P.E.}}$  and the number of total deaths  $D(\text{full})_a^{\text{P.E.}}$  (both include crisis-related deaths and were obtained from the UN IGME 2023 results (27), not part of the modelling process) to derive the point estimates of sex-specific mortality  $Q(\text{full})_a^{\text{P.E.}[\text{sex}]}$  and point estimates of sex-specific deaths  $D(\text{full})_a^{\text{P.E.}[\text{sex}]}$  using the same procedure in Section 3.4.

**Sex-specific deaths to be consistent with total deaths** Due to rounding (Section 3.6.2) and the birth-week cohort method, the sum of the sex-specific deaths for a particular country-year  $D(\text{full})_a^{\text{PE.[F]}} + D(\text{full})_a^{\text{PE.[M]}}$  may be slightly different than the total deaths for the same country-year  $D(\text{full})_a^{\text{PE.}}$ , where total deaths computation is not part of the modelling process. When the inconsistency occurs for a certain country-year, we take the difference between  $D(\text{full})_a^{\text{PE.[F]}} + D(\text{full})_a^{\text{PE.[M]}}$  and  $D(\text{full})_a^{\text{PE.}}$  and distribute it proportionally to the sex-specific deaths. This adjustment is typically small but ensures that  $D(\text{full})_a^{\text{PE.[F]}} + D(\text{full})_a^{\text{PE.[M]}} = D(\text{full})_a^{\text{PE.}}$  for all country-years. We adjust point estimates but not the uncertainty intervals.

### 3.6.4 Imputing results for countries without data

Estimates for countries without data were imputed from the model assumptions and parameter estimates. They were based on the expected sex ratios (determined by the national-level mortality rate for that country), the uncertainty in country-specific deviations based on simulations of the country-year-specific multiplier (that captured the variability unexplained by the expected sex ratios), and the uncertainty in national-level mortality rates.

## 4 Validation exercise and results

We validate the model performance by leaving out data collected after a particular year, referred to as the “survey year”, rather than randomly leaving out data. This validation approach has been used in various previous global health and population studies (35; 23; 36; 37; 38; 39; 40; 41). The left-out observations are roughly 20% of the total observations (due to the varying number of observations collected in each survey year, the left-out observations can be slightly above or below 20%). We call the left-out observations “testing dataset” and the remaining observations “training dataset”.

For each left-out observation in the testing dataset, we generate a posterior predictive distribution based on the Bayesian model fittings for the training dataset. We compute the error as the difference between the left-out observation and the median of the posterior predictive distribution. We report the median errors of all the left-out observations and the median of the absolute errors. We also report the coverage of the 90% prediction intervals (PIs). The lower and upper bound of the 90% PI for each left-out observation is the 5th and 95th percentiles of the posterior predictive distribution. To summarise the coverage, we compute the proportion of left-out observations that fall outside the 90%

We also validate the model performance by comparing the model estimates based on the full and training datasets. We compute the error for each country-year as the difference between the median estimates based on the full dataset and those based on the training dataset. We report the median of these errors and absolute errors for all the country-years. We check the percentage of the country-years where the median estimates based on the full dataset fall outside the credible bounds of the estimates based on the training dataset. Table 8 shows the results for the comparison between estimates obtained based on the full dataset and estimates based on the training set. Median errors and the median absolute errors were close to zero, and the proportion of updated estimates that fell outside the uncertainty intervals constructed based on the training set was small.

Age group	5–9	10–14	15–19	20–24
Median error	-0.04	-0.07	-0.04	-0.02
Median absolute error	0.30	0.33	0.35	0.40
% of left-out observations below 90% prediction interval	4.3	5.5	3.8	3.5
% of left-out observations above 90% prediction interval	4.0	2.8	1.6	1.0
<b>Expected proportions (%)</b>	<b>5</b>	<b>5</b>	<b>5</b>	<b>5</b>
# left out observations	1,083	1,061	965	961

Median error	-0.00	-0.00	-0.00	-0.00	-0.00	-0.01
Median absolute error	0.01	0.01	0.03	0.01	0.02	0.04
Below 90% uncertainty interval (%)	0.0	0.5	1.5	0.0	1.0	1.0
Above 90% uncertainty interval (%)	0.0	0.0	0.0	0.0	0.0	0.0
<b>Expected proportions (%)</b>	<b>≤5</b>	<b>≤5</b>	<b>≤5</b>	<b>≤5</b>	<b>≤5</b>	<b>≤5</b>

Table 8: **Summary of differences in sex ratio estimates in observation years 2000, 2005, and 2010 based on the training and full data sets.** Errors are the differences between estimates based on the full dataset and the training set. The proportions refer to the proportions (%) of countries where the median sex ratio estimates based on the full data set fall below or above their corresponding 90% uncertainty intervals based on the training dataset. The results are broken down by age groups and observation years.

## 5 Global expected sex ratios by age group

Figure 3 illustrates the expected sex ratios for total mortality based on the global relationship between mortality levels and sex ratios for the 0–4, 5–14, and 15–24 age groups. Similar patterns occur for all age groups; as the total mortality declines, the sex ratio initially increases until it reaches a maximum, followed by a slight reduction when the total mortality further decreases.

## 6 Discussion on adding covariates in Bayesian models

Our main objective with this study was to produce robust estimates of sex-specific mortality using a model that does not use covariates. We could have included generic covariates such as GDP per capita, adult literacy rate, indicators related to cause-of-death distribution such as the prevalence of HIV (42) or maternal mortality ratio (43), and sex-specific indicators such as the difference between female and male expected years of schooling or the male and female estimated earned income, sex-specific mortality related/due to infectious diseases, especially zoonotic diseases (44; 45), or information on sex differentials in health status such as nutrition, immunisation (46). This could have improved the estimation, but many aforementioned covariates are unavailable for all countries worldwide or result from complex modelling. Furthermore, the set of covariates would need to change for each age group. In addition, the resulting estimates would no longer be helpful to pinpoint countries with outlying sex ratios (as covariates could affect this outlying situation), and we would no longer be in a position to relate the sex ratios to these potential drivers (as this would be circular).

With our parsimonious model, we only make use of a strong and well-established relationship between overall mortality and the sex ratio, and we can, therefore (1) coherently estimate sex ratios from birth to age 25, and (2) produce robust estimates of sex-specific mortality which can now be analysed in relation to these drivers.

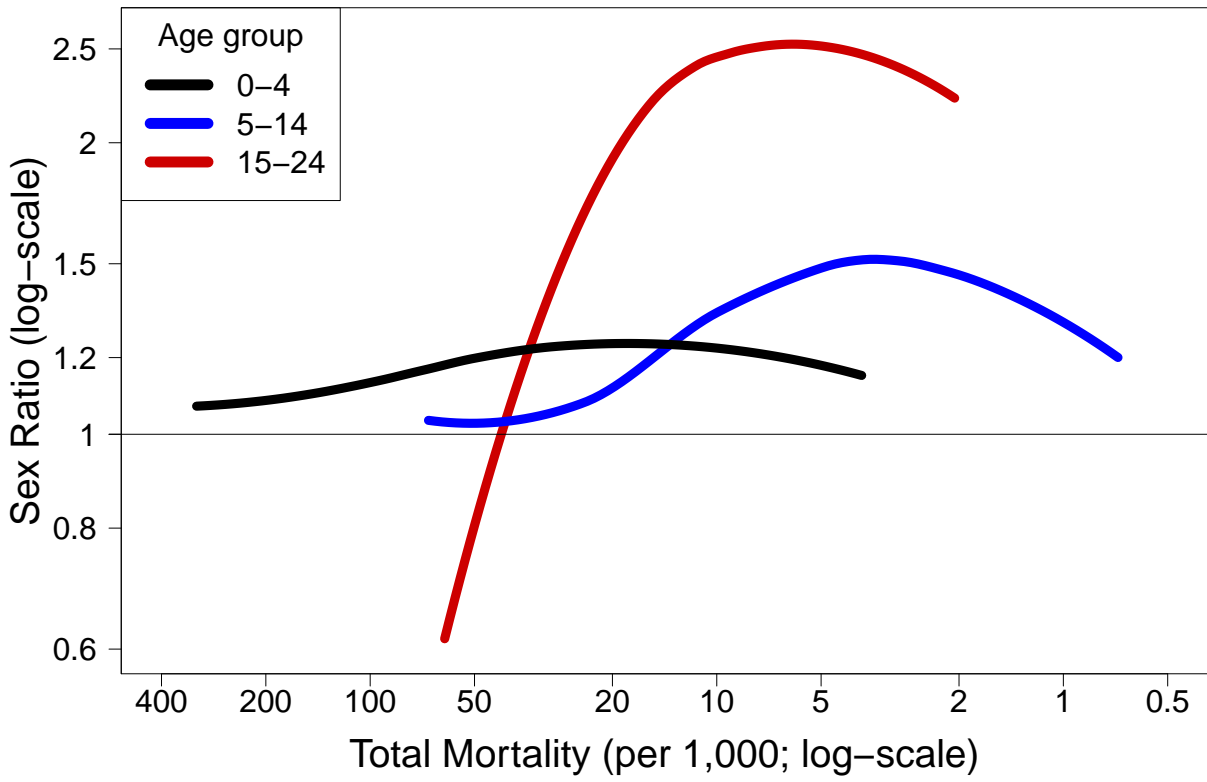

Figure 3: **Overview of the global relations between sex ratios and total mortality levels.** The curves illustrate the relation between sex ratios and total mortality based on the Bayesian models.

## 7 GATHER Compliance

Guidelines for Accurate and Transparent Health Estimates Reporting (GATHER) are reported in Table 9.

Table 9: **Checklist of information that should be included in new reports of global health estimates.** M: main manuscript. A: Appendix. Section titles after “M” are stated for the main manuscript. Page numbers after “A” are shown for the appendix.

Item #	Checklist item	Reported on page # or section #
<b>Objectives and funding</b>		
1	Define the indicator(s), populations (including age, sex, and geographic entities), and time period(s) for which estimates were made.	M-Introduction
2	List the funding sources for the work.	M-Summary
<b>Objectives and funding</b>		
<i>For all data inputs from multiple sources that are synthesized as part of the study:</i>		
3	Describe how the data were identified and how the data were accessed.	M-Database construction, A1–4
4	Specify the inclusion and exclusion criteria. Identify all ad-hoc exclusions.	M-Database construction, A4
5	Provide information on all included data sources and their main characteristics. For each data source used, report reference information or contact name/institution, the population represented, data collection method, year(s) of data collection, sex and age range, diagnostic criteria or measurement method, and sample size, as relevant.	A69–200
6	Identify and describe any categories of input data that have potentially important biases (e.g., based on characteristics listed in item 5).	A1–4
<i>For data inputs that contribute to the analysis but were not synthesized as part of the study:</i>		
7	Describe and give sources for any other data inputs.	M-Database construction, A1, A69–200
<i>For all data inputs:</i>		
8	Provide all data inputs in a file format from which data can be efficiently extracted (e.g., a spreadsheet rather than a PDF), including all relevant meta-data listed in item 5. For any data inputs that cannot be shared because of ethical or legal reasons, such as third-party ownership, provide a contact name or the name of the institution that retains the right to the data.	M-Database construction
<b>Data analysis</b>		
9	Provide a conceptual overview of the data analysis method. A diagram may be helpful.	M-Database construction, A5
10	Provide a detailed description of all analysis steps, including mathematical formulae. This description should cover, as relevant, data cleaning, data pre-processing, data adjustments and weighting of data sources, and mathematical or statistical model(s).	M-Statistical analysis, A1–11
11	Describe how candidate models were evaluated and how the final model(s) were selected.	M-Statistical analysis, A13

Table 22: **Sex ratio data sources for age group 0–1, by country.** For each country, the total number of observations and the most recent reference year are shown after the country name. For each country-specific data series, the number of observations and the most recent reference year within that series is shown before each data series name. The source type that each data series falls in is shown in parentheses after each data series name.

Table 23: **Sex ratio data sources for age group 1–4, by country.** For each country, the total number of observations and the most recent reference year are shown after the country name. For each country-specific data series, the number of observations and the most recent reference year within that series is shown before each data series name. The source type that each data series falls in is shown in parentheses after each data series name.

Table 24: **Sex ratio data sources for age group 0–4, by country.** For each country, the total number of observations and the most recent reference year are shown after the country name. For each country-specific data series, the number of observations and the most recent reference year within that series is shown before each data series name. The source type that each data series falls in is shown in parentheses after each data series name.

Table 25: **Sex ratio data sources for age group 5–9, by country.** For each country, the total number of observations and the most recent reference year are shown after the country name. For each country-specific data series, the number of observations and the most recent reference year within that series is shown before each data series name. The source type that each data series falls in is shown in parentheses after each data series name.

Table 26: **Sex ratio data sources for age group 10–14, by country.** For each country, the total number of observations and the most recent reference year are shown after the country name. For each country-specific data series, the number of observations and the most recent reference year within that series is shown before each data series name. The source type that each data series falls in is shown in parentheses after each data series name.

Table 27: **Sex ratio data sources for age group 15–19, by country.** For each country, the total number of observations and the most recent reference year are shown after the country name. For each country-specific data series, the number of observations and the most recent reference year within that series is shown before each data series name. The source type that each data series falls in is shown in parentheses after each data series name.

Table 28: **Sex ratio data sources for age group 20–24, by country.** For each country, the total number of observations and the most recent reference year are shown after the country name. For each country-specific data series, the number of observations and the most recent reference year within that series is shown before each data series name. The source type that each data series falls in is shown in parentheses after each data series name.
